Stochastic Gradient Descent (SGD)

and Stochastic Differential Equations (SDEs)

Modeling the SGD as a Stochastic Process

If we randomly select training points then SGD is a stochastic process.

Can we analytically solve for stationary distributions?

Is the stationary distribution Gibbs — is it $\frac{1}{Z}e^{-\frac{\mathcal{L}}{kT}}$ where the temperature T is determined by the learning rate?

Modeling the SGD as a Stochastic Process

It is possible to model both the stationary distribution and non-stationary stochastic dynamics with a continuous time stochastic differential equation such as Brownian motion or Langevin Dynamics.

Langevin Dynamics is the special case where the stationary distribution is Gibbs.

We will show here that in general the stationary distribution of SGD is not Gibbs and hence does not correspond to Langevin dynamics.

Holding η Fixed

Consider SGD with batch size 1.

$$\Phi_{i+1} = \Phi_i - \eta \hat{g}_i$$

Unlike gradient flow, we now hold $\eta > 0$ fixed.

We will still take "time" to be the sum of the learning rates over the updates.

For N steps of SGD we define $\Delta t = N\eta$

Holding η Fixed

We consider Δt large enough so that Δt corresponds to many SGD updates.

We consider Δt small enough so that the gradient estimate distribution does not change over the interval Δt.

Applying the Law of Large Numbers

If the mean gradient $g(\Phi)$ is approximately constant over the interval $\Delta t = N\eta$ we have

$$\Phi(t + \Delta t) \approx \Phi(t) - g(\Phi)\Delta t + \eta \sum_{i=1}^{N} (g(\Phi) - \hat{g}_i)$$

The random variables in the last term have zero mean.

By the law of large numbers a sum (not the average) of N random vectors will approximate a Gaussian distribution where the standard deviation grows like $\sqrt{N}$.

Applying the Law of Large Numbers

For $\epsilon \sim \mathcal{N}(0, \Sigma)$ where Σ is the covariance matrix of the random variable $\hat{g}$ we have

$$\begin{aligned}
\Phi(t + \Delta t) &\approx \Phi(t) - g(\Phi)\Delta t + \eta \sum_{j=1}^{N} (g(\Phi) - \hat{g}_i) \\
&\approx \Phi(t) - g(\Phi)\Delta t + \eta\epsilon\sqrt{N} \\
&= \Phi(t) - g(\Phi)\Delta t + \eta\epsilon\sqrt{\frac{\Delta t}{\eta}}
\end{aligned}$$

The Stochastic Differential Equation (SDE)

$$\Phi(t+\Delta t) \approx \Phi(t) - g(\Phi)\Delta t + \epsilon\sqrt{\eta\Delta t} \qquad \epsilon \sim \mathcal{N}(0,\Sigma)$$

$$= \Phi(t) - g(\Phi)\Delta t + \epsilon\sqrt{\Delta t} \qquad \epsilon \sim \mathcal{N}(0,\eta\Sigma)$$

We can take this last equation to hold in the limit of arbitrarily small Δt in which case we get a continuous time stochastic process. This process can be written as

$$d\Phi = -g(\Phi)dt + \epsilon\sqrt{dt} \qquad \epsilon \sim \mathcal{N}(0,\eta\Sigma)$$

The Stochastic Differential Equation

$$d\Phi = -g(\Phi)dt + \epsilon\sqrt{dt} \qquad \epsilon \sim \mathcal{N}(0, \eta\Sigma)$$

For $g(\Phi) = 0$ and $\Sigma = I$ we get Brownian motion.

For a general loss function and $\Sigma = I$ we get Langevin Dynamics and a Gibbs stationary distribution.

But in general we do not have $\Sigma = I$.
