Speech Recognition

Connectionist Temporal Classification (CTC)

Connectionist Temporal Classification (CTC)

Connectionist Temporal Classification: Labelling Unsegmented Sequence Data with Recurrent Neural Networks

Alex Graves, Santiago Fernández, Faustino Gomez, Jürgen Schmidhuber, ICML 2006

This is currently the dominant approach to speech recognition.

CTC

In CTC a graphical model is computed by a deep network where the probability of the gold label in that model can be computed exactly by dynamic programming.

When the loss can be computed exactly one can simply back-propagate on the loss computation.

Later we will consider cases where computing the loss exactly is intractible.

CTC

A speech signal $x[T, J]$ is labeled with a phone sequence $y[N]$ with $N \ll T$.

$x[t, J]$ is a speech signal vector.

$y[n] \in \mathcal{P}$ for a set of phonemes \mathcal{P} .

The length N of $y[N]$ is not determined by T and the correspondence between n and t is not given.

$$\Phi^* = \underset{\Phi}{\operatorname{argmin}} E_{\langle x, y \rangle \sim \text{Train}} -\ln P_{\Phi}(y[N] \mid x[T, J]) \quad N \ll T$$

The CTC Model

We define a model

$$P_{\Phi}(z[T] \mid x[T, J])$$

$$z[t] \in \mathcal{P} \cup \{\perp\}$$

$y[N]$ is the result of removing \perp from $z[T]$.

$$z[T] \Rightarrow y[N]$$

$$\perp, a_1, \perp, \perp, \perp, a_2, \perp, \perp, a_3, \perp \Rightarrow a_1, a_2, a_3$$

The CTC Model

For $p \in \mathcal{P} \cup \{\perp\}$ we have an embedding vector $e[p, I]$. The embedding is a parameter of the model.

We take the phonemes $z[t]$ to be independently distributed.

$$p_{\Phi}(Z[T] \mid x[T, J]) = \prod_t P_{\Phi}(z[t] \mid x[T, J])$$

$$h[T, \tilde{J}] = \text{RNN}_{\Phi}(x[T, J])$$

$$P_{\Phi}(z[t] \mid x[T, J]) = \underset{z[t]}{\text{softmax}} \ e[z[t], I] \ W[I, \tilde{J}] \ h[t, \tilde{J}]$$

Dynamic Programming

Let $\vec{y}[t]$ to be the prefix of $y[N]$ emitted by the first t elements of z .

$$\vec{y}[t] = z[1 : t] - \perp$$

$$F[n, t] = P(\vec{y}[t] = y[1 : n])$$

$$F[0, 0] = 1$$

$$\text{For } n = 1, \dots, N \quad F[n, 0] = 0$$

$$\text{For } t = 1, \dots, T$$

$$F[0, t] = P(z[t] = \perp)F[0, t - 1]$$

$$\text{For } n = 1, \dots, N$$

$$F[n, t] = P(z[t] = \perp)F[n, t - 1] + P(z[t] = y[n])F[n - 1, t - 1]$$

Back-Propagation

$$\mathcal{L} = -\ln F[N, T]$$

We can now back-propagate through this computation.
